- AB Base-catalyzed reactions of di-Et [(oxiranylmethoxy)methyl]phosphonate (I) with purine bases (adenine, 2,6-diaminopurine, 6-chloropurine and 2-amino-6-chloropurine) gave corresponding 9- or 7-[2-hydroxy-3-(phosphonomethoxy)propyl] purines. The adenine and 2,6-diaminopurine derivs. cyclize to cyclic phosphonates II (R2 = H, NH2). The 9-[2-hydroxy-3-(phosphonomethoxy)propyl] derivs. of N6-substituted adenine and 2,6-diaminopurine were prepared by the treatment of di-Et {[3-(6-chloropurin-9-yl)-2-hydroxy-propoxy]methyl}phosphonate (III; R3 = H) or di-Et {[3-(2-amino-6-chloropurin-9-yl)-2-hydroxy-propoxy]methyl}phosphonate (III; R3 = NH2) with primary or secondary amines. The reaction of 6-chloro- or 2-amino-6-chloropurine derivs. III with thiourea gave the corresponding di-Et purine-6-thiol or 2-aminopurine-6-thiol phosphonates IV (R4 = H, NH2; X = S). The guanine derivative IV (R4 = NH2; X = O) was prepared by the treatment of III (R3 = NH2) with 80% acetic acid. All di-Et phosphonates were transformed to free phosphonic acids by the action of bromotrimethylsilane and subsequent hydrolysis.

* STRUCTURE DIAGRAM TOO LARGE FOR DISPLAY - AVAILABLE VIA OFFLINE PRINT *

AB A new labeling technique attaching fluorescein via a carbamoyl linker directly to the amino groups of the nucleobases was developed. The amino groups were first converted to the phenoxycarbonyl derivs., which reacted under mild conditions with 5-aminofluorescein to give the corresponding N-[(fluorescein-5-ylamino)carbonyl] derivs. The introduction of the 5-aminofluorescein residue into properly protected adenylyl-adenosine dimers and trimer worked well, and final deprotection of these uniformly blocked precursors led on treatment with DBU (1,8-diazabicyclo[5.4.0]undec-7-ene), in one step to dimer and trimer. Synthesis of an appropriately protected monomeric phosphoramidite building block I [R = dimethoxytrityl, R1 = P{N(CHMe2)2}OCH2CH2C6H4NO2-4, R2 = R3 = npe, R4 = H; npe = CH2CH2C6H4NO2-4] was more difficult, since introduction of the 2-(4-nitrophenyl)ethyl residue into the fluorescein moiety in I [RR1 = Si(CHMe2)2OSi(CHMe2)2, R2 = R3 = npe, R4 = H] led mainly to trisubstitution to give I [RR1 = Si(CHMe2)2OSi(CHMe2)2, R2 = R3 = R4 = npe] including the urea function. Formation of the adenylyl dimer II (R = H; npeoc = CO2CH2CH2C6H4NO2-4) and trimer II (R = R') proceeded in the usual manner by phosphoramidite chemical; however, deprotection of II (R = R') with DBU was incomplete since the O-alkyl group at the urea moiety was found to be very stable. Finally, the appropriate phosphoramidite building block I [R = dimethoxytrityl, R1 = P{N(CHMe2)2}OCH2CH2C6H4NO2-4, R2 = R3 = npe, R4 = H; npe = CH2CH2C6H4NO2-4] could be synthesized by the sequence I [R = dimethoxytrityl, R1 = P{N(CHMe2)2}OCH2CH2C6H4NO2-4, R2 = R3 = npe, R4 = H; npe = CH2CH2C6H4NO2-4] → I [R = dimethoxytrityl, R1 = P{N(CHMe2)2}OCH2CH2C6H4NO2-4, R2 = R3 = npe, R4 = H]. The phosphoramidite I [R = dimethoxytrityl, R1 = P{N(CHMe2)2}OCH2CH2C6H4NO2-4, R2 = R3 = npe, R4 = H] was used for the synthesis of a dimer and a trimer by solution chemical, as well as for that of various oligonucleotides by the machine-aided approach on solid support carrying the fluorophore at different positions of the chain. The attachment of the fluorescein fluorophore via a short carbamoyl linker onto the 6-amino group of 2'-deoxyadenosine enables such mols. to function very well in fluorescence-polarization expts.

AB Paleatin B, an open chain bis(bibenzyl) constituent of Marchantia paleacea var. diptera methoxylated at one of the ethano bridges was synthesized. The key steps were the alkylation of a 2-aryl-1,3-dithiane (11) with a benzyl bromide (9) and transformation of a benzyl alc. (17) to a benzyl Me ether by acid catalyzed methanolysis.

AB In the presence of KF-2H₂O di-Me phosphite adds preferentially (d.e. 50%) to the si face of the carbonyl group of chalcone epoxide I. Under acidic conditions the oxirane ring in the major α -hydroxy- β,γ -epoxyphosphonate (1S*,2S*,3R*)-II (R = OH, R₁ = P(O)(OMe)₂) is regio- but not stereoselectively cleaved with methanol and/or water, while the minor one (1R*,2S*,3R*)-II (R = P(O)(OMe)₂, R₁ = OH) undergoes intramol. cyclization to form 1,2-oxaphospholan-3,4-diols with full stereoselectivity.

AB Hydrolytic reactions of the cis-Ph ester of thymidine 3',5'-cyclic monophosphate have been followed by HPLC over a wide pH range. The product analyses of the corresponding **methanolysis** reactions suggest that the pH-independent reaction predominantly takes place via cleavage of the C5'O bond, while the alkaline reaction proceeds by rupture of one of the PO bonds.

AB Based upon dithiaphospholane method the new approach to the synthesis of dithymidine-3',5''-phosphorothioselenoate (mixture of two P-diastereomers) was established. Methylation of these compds. occurred exclusively at selenium atom and obtained methylselenyl esters under treatment with fluoride ion gave dithymidine-3',5''-phosphorothiofluoridates as the mixts. of both P-stereoisomers. Their base-catalyzed hydrolysis and **methanolysis** led to dithymidine-3',5''-phosphorothioates and dithymidine-3',5''-(O-methyl)phosphorothioates, resp. In this communication authors present their results supporting the extended scope

of oxathia-and dithiaphospholane chemical in its application to the synthesis of dithymidine-3',5'-phosphorothioate (I; X = F, R = DMT, R1 = Ac). Thus, thymidine 3'-O-(2-seleno-1,3,2-dithiaphospholane) derivative (II) in the DBU-assisted reaction with 3'-O-acetylthymidine gave dithymidine-3',5''-phosphorothioselenothioate derivative I (X = Se-1, R = DMT, R1 = Ac) which underwent chemoselective alkylation by MeI at selenium to give Se-Me dithymidine-3',5''-phosphorothioselenothioate derivative I (X = MeSe, R = DMT, R1 = Ac). Treatment of the latter compound with AgF in aqueous MeCN or triethylammonium fluoride [Et3N(HF)3] in THF produced dithymidine-3',5''-phosphorothiofluoridate derivative I (X = F, R = DMT, R1 = Ac), which underwent complete hydrolysis in 1 M NH4OH within 15 min to give a diastereomeric mixture of dithymidine-3',5''-phosphorothioate derivative I (X = O-1, R = DMT, R1 = Ac). The same compound I (X = F, R = DMT, R1 = Ac) reacted smoothly with MeOH in the presence of Et3N or pyridine to give O-Me dithymidine-3',5''-phosphorothioate derivative I (X = MeO, R = DMT, R1 = Ac). The susceptibility of I (X = F, R = DMT, R1 = Ac) to hydrolysis in aqueous media, and especially, fast hydrolysis in concentrated ammoniacal solution, limits the oligonucleotides containing internucleotide functions modified with phosphorothiofluoridate moieties from the general use as antisense agents. With regard to author's interest in enzymic studies, authors also prepared the so far uncharacterized, fully deprotected dithymidine-3',5''-phosphorothiofluoridate I (X = F, R = R1 = H) (III). Enzymic studies on substrate specificity and/or inhibitory effect of III for the snake venom phosphodiesterase and nuclease P1 are in progress.

AB A series of phosphonoalkenyl and (phosphonoalkenyl)oxy derivs. of purines and pyrimidines were synthesized. These compds. are the first reported acyclonucleotides which incorporate the α,β -unsatd. phosphonic acid moiety as the phosphate mimic and include compds. in which the acyclic substituent is attached to N(9) of a purine or N(1) of a pyrimidine by either a nitrogen-carbon or a nitrogen-oxygen bond. The phosphonoalkenyl-substituted compds. I [R = CH₂CH₂CH:CHP(O)(OH)₂-(E), -(Z), CH₂CH(CH₂OH)CH:CHP(O)(OH)₂], II [R = CH₂CH₂CH:CHP(O)(OH)₂-(E), -(Z), CH₂CH(CH₂OH)CH:CHP(O)(OH)₂], CH₂C(:CH₂)CH:CHP(O)(OH)₂-(E)], III and IV [R₁ = CH₂CH(CH₂OH)CH:CHP(O)(ONa)₂-(E)] were prepared either by Mitsunobu

coupling of alcs. with purine or pyrimidine derivs. or by alternative alkylations of the heterocyclic bases. The (phosphonoalkenyl)oxy derivs. I [R = OCH₂CH₂CH:CHP(O)(OH)₂-(E), -(Z), OCH₂CH(CH₂OH)CH:CHP(O)(OH)₂-(E), OCH(CH₂OH)CH:CHP(O)(OH)₂-(E)], II [R = OCH₂CH₂CH:CHP(O)(OH)₂-(E), -(Z), OCH₂CH(CH₂OH)CH:CHP(O)(OH)₂-(E), OCH(CH₂OH)CH:CHP(O)(OH)₂-(E)], and IV [R₁ = OCH(CH₂OH)CH:CHP(O)(OH)₂-(E)] were synthesized by coupling of alcs. with 9-hydroxypurines or a 1-hydroxypyrimidine under Mitsunobu conditions. The novel acyclonucleotides were tested for activity against herpes simplex types 1 and 2 (HSV-1 and HSV-2), varicella zoster virus (VZV), cytomegalovirus (CMV), visna virus, and human immunodeficiency virus type 1 (HIV-1). Guanine derivs. were moderately to extremely cytotoxic, but the adenines were less toxic to cells. At the concns. tested, (Z)-isomers in the unbranched series had no activity against herpes viruses and HIV-1. (E)-9-[(4-Phosphonobut-3-enyl)oxy]adenine [I; R = OCH₂CH₂CH:CHP(O)(OH)₂-(E)] displayed selective activity against HIV-1, (E)-2,6-diamino-9-(4-phosphonobut-3-enyl)purine (III) showed selective antiretrovirus activity, and (E)-9-[2-(hydroxymethyl)-4-phosphonobut-3-enyl]adenine [I; R = CH₂CH(CH₂OH)CH:CHP(O)(OH)₂-(E)] showed selective antiherpes virus (VZV and CMV) activity.

AB Treatment of 3,4,5,7-tetra-O-acetyl-2,6-anhydro-D-glycero-D-galacto-

heptononitrile with diazabicycloundecene (BDU) formed 4,5,7-tri-O-acetyl-2,6-anhydro-3-deoxy-D-arabino-hept-2-enonitrile, which on treatment with NH_4N_3 gave the tetrazole. Stereoselective catalytic reduction of the tetrazole and deacetylation produced 5-(2-deoxy- β -D-arabino-hexopyranosyl)tetrazole, which was converted in two steps into its 6-phosphate. Reaction of 4,5,7-tri-O-acetyl-2,6-anhydro-3-deoxy-D-manno-heptononitrile with NH_4N_3 , followed by deacetylation, gave 5-(2-deoxy- α -D-arabino-hexopyranosyl)tetrazole (81% overall), which was converted into its 6-phosphate. When 4,5,7-tri-O-acetyl-2,6-anhydro-2-bromo-3-deoxy-D-gluco-heptononitrile was treated with MeOH and 2,6-lutidine, Me 3,4,6-tri-O-acetyl-1-cyano-2-deoxy- β -D-arabino-hexopyranoside (I) was obtained (40%) together with the α -anomer (11%). Cycloaddn. of I with azide, followed by sequential treatment with base and with acid, gave 2-deoxy-1-tetrazol-5-yl- α -D-arabino-hexopyranose (54% overall). Treatment of 1,3,4,6-tetra-O-acetyl-2-deoxy- α -D-lyxo-hexopyranose with Me_3SiCN and BF_3 in MeNO_2 gave 4,5,7-tri-O-acetyl-2,6-anhydro-3-deoxy-D-talo-heptononitrile (II, 53%), together with the D-galacto-epimer (17%). Cycloaddn. of these compds. with azide and deprotection gave 5-(2-deoxy- β -D-lyxo-hexopyranosyl)tetrazole and the α -D-lyxo-isomer resp. in good yields. Reaction of II with N-bromosuccinimide formed 4,5,7-tri-O-acetyl-2,6-anhydro-2-bromo-3-deoxy-D-galacto-heptononitrile (63%), which with MeOH and 2,6-lutidine was converted into the Me β -D-glycoside. Cycloaddn. of the glycoside with azide, deacetylation, and hydrolysis led to 2-deoxy-1-tetrazol-5-yl- α -D-lyxo-hexopyranose. None of the C-glycosyltetrazoles were strong inhibitors of dehydroquinase synthase from *E. coli*.

AB Synthesis of the phosphate esters of several benzoin, variously substituted with methoxy groups in one or both aromatic rings, proceeds via the corresponding cyclic ethylene ketals. These are phosphitylated with bis-(2-cyanoethyl) diisopropylphosphoramidite and the phosphites are oxidized to phosphates. Cleavage of the 2-cyanoethyl groups with methanolic alkali, followed by acid-catalyzed hydrolysis of the ethylene ketal, yields the required phosphate monoesters. Application of the same reaction sequence to benzoin itself, not protected as the cyclic ketal, leads to at least three products, a phosphate monoester, a phosphate diester, and a substance not containing phosphorus, which appeared to be a ketal. The likely origin of these three products is discussed. The potential of these phosphate esters and their derivs. for study of rapid biochem. processes by fast photochem. cleavage of the benzoin group was examined. Best results were obtained with a 3',5'-dimethoxybenzoin phosphate, where a single pulse of 347 nm light (100 mJ in 50 ns) resulted in 10% conversion into products, with first-order rate constant > 10⁵ s⁻¹.

AB A fifteen-step synthesis of the proposed purine nucleoside phosphorylase (PNP) transition state analog inhibitor 9-(1-deoxy-1-phosphono- β -D-psicofuranosyl)-1,9-dihydro-H-purine-6-one (I) is described starting with 1,2:4,5-diisopropylidene- β -D-psicopyranose (II). Catalytic hydrogenation of 9-[3-O-benzyl-1-(dibenzoyloxyphosphinyl)-1-deoxy- β -D-psicofuranosyl]-6-benzoyloxypurine (III) under basic conditions gave the unstable I which was found to have a half-life of 39 min at pH 7 and 81 min at pH 8. The low PNP inhibitory activity found for I (IC_{50} = 25 μ M at 50 mM phosphate concentration) may be due entirely to the presence of the decomposition product hypoxanthine which is itself an inhibitor (IC_{50} = 8.6 μ M).

AB Addition of alkali dialkyl phosphites NaOP(OR)_2 ($\text{R} = \text{Me, Et, CHMe}_2, \text{Bu}$) to benzylidenedihydrooxazolones I [$\text{R}_1 = \text{Ph, 4-MeOC}_6\text{H}_4, 3,4\text{-(MeO)}_2\text{C}_6\text{H}_3$] gave phosphorylmethyl derivs. II ($\text{R}_2 = \text{Na}$), which reacted with Me_3SiCl to give siloxy derivs. II ($\text{R}_2 = \text{SiMe}_3$). Treatment of II ($\text{R}_2 = \text{SiMe}_3$) with water or alcs. gave the title compds. $\text{R}_2\text{O}_3\text{PCHR}_1\text{CH(NHBz)CO}_2\text{R}_3$ (III; $\text{R}_3 = \text{H, Me, Et}$). The ratio of diastereomers of III depends on the reaction conditions, with different diastereoselectivity observed in basic and acidic conditions. The proposed reaction pathway is supported by characterization of intermediate dialkylphosphorylmethyloxazolone IV [$\text{R} = \text{Et, R}_1 = 3,4\text{-(MeO)}_2\text{C}_6\text{H}_3$]. Complete hydrolysis of III [$\text{R} = \text{Et, R}_1 = 3,4\text{-(MeO)}_2\text{C}_6\text{H}_3, \text{R}_3 = \text{Me}$] gave 3-phosphonoaspartic acid $\text{H}_2\text{O}_3\text{PCHR}_1\text{CH(NH}_2\text{)CO}_2\text{H.HCl}$ ($\text{R}_1 = \text{same}$).

AB Title derivs. I (R = N-protecting group; R₁ = H, aryl, alkyl; R₂ = H, halo; trans/cis ≥ 90:10) are prepared by Friedel-Crafts-type reaction of cis proline derivs. II (X = leaving group) with benzene, a halobenzene, or PhSiMe₃ in the presence of a Lewis acid catalyst at 5-80° under an inert atmosphere. The mol ratio of II to aromatic compound to catalyst is 1:(5-100):(2-10). For example, trans-4-hydroxy-L-proline was subjected to a sequence of N-benzoylation, Me esterification, O-tosylation, saponification, lactonization, **methanolysis**, O-mesylation, and saponification to give II (R = Bz, R₁ = H, X = MeSO₃). The mesylate was added to excess benzene and AlCl₃, followed by stirring for 7 h at room temperature, cooling, hydrolysis, and workup (2 crops) to give 81% I (R = Bz, R₁ = R₂ = H). Preps. of a variety of I and II are described.

AB 5-Azido-1-phenyltriazoles I [R = CHO, CH:NR₁, 4-ClC₆H₄, 4-O₂NC₆H₄, PO(OEt)₂, PhSO₂; R₁ = Ph, 4-MeOC₆H₄, 4-ClC₆H₄, Et, CMe₃, CH₂Ph, OH) can thermally isomerize to diazo substituted tetrazoles II or decompose to alkylidenetetrazenes RC(CN):NN:NPh, depending on the nature of the substituent at the 4-position. The former are obtained for electron-withdrawing substituents [CHO, CH:NR₁, PO(OEt)₂, PhSO₂], whereas the latter are formed with aryl substituents. The diazo compds. II were stable and isolable when R = CHO or PO(Et)₂, but they ring-closed to triazoles III when R = CH:NR₁, or they decomposed under the reaction conditions to cycloheptatrienes, e.g. IV, when R = PhSO₂. A kinetic study of the rearrangement has been carried out and the mechanism is discussed.

AB Pyrimidine derivs. I [R1 = H, F, Cl; R2 = R1, C1-4 alkyl, C1-6 alkoxy, 2-propenyloxy, 2-propynyloxy, 2-(C1-4 alkoxy)ethoxy, halo (un)substituted PhO, C1-6 alkylthio, alkylamino, di(C1-4 alkyl)amino, OC(Z1)NR6R7, OP(S)(OR8)(OR9); R3 = R1, C1-6 alkyl, C3-6 cycloalkyl, (C1-4 alkoxy)methyl, (C1-4 alkylthio)methyl, C1-6 alkoxy, 2-propenyloxy, 2-propynyloxy, C1-6 alkylthio, C1-4 alkylamino, di(C1-4 alkyl)amino, Ph (un)substituted with F, Cl, CF3, and(or) MeO; R4 = C1-3 alkyl; R5 = C1-6 alkyl; R6 and R7 or R8 and R9 independently = C1-3 alkyl; Z, Z1 independently = O, S], useful as insecticides, nematocides, and acaricides (no data), were prepared by many methods. O-Alkylating 4-hydroxy-6-(chloromethyl)-2-methylpyrimidine with (EtO)2SO2 and K2CO3 in refluxing Me2CO 6 h gave the 4-ethoxy analog which reacted with KSP(O)(OEt)SPr in Me2CO containing a small amount of NaI 12 h at 45° to give I (R1 = H, R2 = EtO, R3 = Me, R4 = Et, R5 = Pr, Z = O).

AB Homoadenosines I [R = CH₂OH, CH₂CH₂OH, CH₂P(O)(OH)₂] were prepared from adenosine II, e.g., II on sequential 5'-O-tosylation, 5'-cyanation, **methanolysis**, and NaBH₄ reduction gave I (R = CH₂OH). The conformational parameters of I were determined from the observed coupling consts. by the method of Altona and Sundoralingam.

AB Carbamoylation of glucal I with HCONH₂ gave a mixture of 3 products containing II (R = CONH₂, R₁ = R₂ = R₃ = Ac), which on sequential **methanolysis** and benzylidenation gave II (R = CO₂Me, R₁ = H, R₂R₃ = PhCH). The latter on NaBH₄ red. followed by iodination with N-iodosuccinimide-Ph₃P and acetylation with Ac₂O-pyridine gave II (R = CH₂I, R₁ = Ac, R₂R₃ = PhCH), which on Arbuzov reaction with (Me₂CHO)₃P gave the phosphonate [II; R = CH₂P(O)(OCHMe₂)₂, R₁ = Ac, R₂R₃ = PhCH]. Phosphonate III was similarly prepared from galactal analog of I.

AB A method for preparing triester alkyl derivs. of oligonucleotides was described which is based on oligonucleotide chlorophenyl ester reaction with amino alcs. in polar organic solvents in the presence of CsF or Bu₄N⁺F⁻. The latter compound is a more effective catalyst than CsF for transesterification. The amino group was inert under conditions of **alcoholysis**. 6-Aminoethyl triester analogs of thymidylyl- and pentathymidylyl-(3'→5')-thymidine were prepared. Complexing with polydeoxyadenylic acid was studied for aminoethyl and Et triester analogs, [Tp(nhx)]5T (nhx = 6-aminoethyl), [Tp(Et)]5T, and for [Tp]5T. A complex formed with pos. charged oligonucleotide [Tp(nhx)]5T had a higher thermal stability than those involving neg. charged [Tp]5T or neutral [Tp(Et)]5T.

AB The synthesis of all mono- and disilyl derivs. of cytidine, guanosine, and their N-benzoyl analogs using the tert-butyldimethylsilyl protecting group is described. These compds. and those containing a 5'-monomethoxytrityl group have been condensed via the phosphodichloridite procedure to give nucleotides rapidly and in good yields. The synthesis of 2'-5'-linked nucleotides is also described. Attempts to prepare 5'-monomethoxytritylguanosine gave instead a compound possessing a methoxytrityl group on the guanine ring, most likely at N2.

Methanolysis of 5'-(methoxytrityl)-2-O-(tert-butyldimethylsilyl)-N4-benzoylcytidine gave 5'-(methoxytrityl)-2-O-(tert-butyldimethylsilyl)cytidine and rearranged 5'-(methoxytrityl)-3-O-(tert-butyldimethylsilyl)cytidine.

IV

AB The stereochem. of the 4 isomers of telomer I, prepared by free-radical telomerization of vinylene carbonate with CCl₄, was established as all-trans addition forms, based on their conversions to the enol phosphates II (R = Me, Et) and heptitols III. Synthetic potential of the telomers for aldoheptoses and aldooctoses was shown by transforming the telomer IV into racemic D-glycero-L-gulo- and D-glycero-D-ido-heptoses and D-threo-D-ido-octose.

AB The treatment of 3'-amino-3'-deoxyadenosine (I) with $\text{PSCl}_3\text{-OP(OEt)}_3$ gave II and III [$\text{R} = \text{R}_2 = \text{H}$, $\text{R}_1 = \text{EtOP(O)(OH)}$]. Similarly, 3'-tert-butoxycarbonylamino-3'-deoxyadenosine (IV) gave V ($\text{X} = \text{O}$, $\text{X}_1 = \text{S}$, $\text{R} = \text{OH}$) (VI), III [$\text{R} = \text{R}_1 = \text{H}$, $\text{R}_2 = (\text{HO})_2\text{P(S)}$] (VII) and 3'-amino-5'-chloro-3',5'-dideoxyadenosine. Treatment of I and IV with $\text{ClP(S)(OC}_6\text{H}_4\text{NO}_2\text{)}_2$ gave III [$\text{R} = \text{R}_2 = \text{H}$, $\text{R}_1 = \text{MeOP(S)(OH)}$] (VIII) and III [$\text{R} = \text{H}$, $\text{R}_1 = \text{Me}_3\text{COC(O)}$, $\text{R}_2 = (4\text{-O}_2\text{NC}_6\text{H}_4\text{O})_2\text{P(S)}$], resp. Reaction of 3',5'-diamino-3',5'-dideoxyadenosine and PSCl_3 gave V ($\text{X} = \text{NH}$, $\text{X}_1 = \text{S}$, $\text{R} = \text{OH}$) (IX). Treatment of II, VI, and VIII with CH_2N_2 gave III [$\text{R} = \text{R}_2 = \text{H}$, $\text{R}_1 = \text{MeOP(O)(OH)}$]. Similarly VII gave III [$\text{R} = \text{R}_1 = \text{H}$, $\text{R}_2 = \text{MeSP(O)(OH)}$] and IX gave V ($\text{X} = \text{NH}$, $\text{X}_1 = \text{O}$, $\text{R} = \text{MeS}$). The structures were determined by their ^{13}C and ^{31}P NMR spectra. The P-N bonds in VI and IX are less susceptible to acidolysis than the corresponding compds. having $\text{P} = \text{O}$ groups.

AB cf. *ibid.* 81-9, 90-8; CA 62, 6547d. 6-Aza-3-diphenylmethyluracil Hg salt (456 mg.) and 2,3-di-O-benzoyl-5-O-diphenylphosphoryl-D-ribofuranosyl bromide (Ia) (from 1.2 millimoles Me riboside) (CA 58, 1459e; Ukita and Hayatsu, CA 57, 9930g) in 35 ml. xylene was refluxed 80 min. to give 85 mg. oily 6-aza(2,3-di-O-benzoyl-5-O-diphenylphosphoryl-β-D-ribofuranosyl)-3-diphenylmethyl-1-uracil, yielding, on hydrogenolysis over 10% Pd/C at 50° for 10 hrs., 71% 6-aza-1-(2,3-di-O-benzoyl-5-O-diphenylphosphoryl-β-D-ribofuranosyl)uracil (I), m. 192-3° (EtOH), [α]_D²⁰ -50.0° (c 0.094, CHCl₃), identical with the product obtained in 42% yield by benzylation of 6-azauridine 5'-(diphenyl phosphate) (II). II was obtained in 17.5-mg. yield when 34.3 mg. I in 5 ml. 0.016M MeONa-MeOH was kept 6 hrs. and neutralized with Dowex 50 W(H⁺). Hydrogenolysis of 68.6 mg. I in MeOH over 50 mg. PtO₂ for 5 hrs. afforded 24.5 mg. 6-azauridine 5'-(phenyl phosphate) (III), while hydrogenolysis of II and III over PtO₂ at 50° for 12 and 8 hrs., resp., gave in both cases 6-azauridine 5'-phosphate, isolated as the Ba salt, along with a by-product identified as 6-aza-5,6-dihydrouridine 5'-phosphate. 6-Aza-5-methyluridine 5'-phosphate (IV) was obtained analogously. Thus, 6-aza-5-methyl-3-diphenylmethyluracil Hg salt (785 mg.) was refluxed 1 hr. with Ia (from 2 millimoles Me riboside) and the product chromatographed repeatedly over (2,3-di-O-benzoyl-5-O-diphenylphosphoryl-β-D-ribofuranosyl)-Al₂O₃ in various solvent systems to give 156 mg. oily 6-aza-5-methyl-3-diphenylmethyluracil (V), yielding on partial hydrogenolysis over 10% Pd/C for 8 hrs. at 45° 85% 6-aza-1-(2,3-di-O-benzoyl-5-methyl-5-O-diphenylphosphoryl-β-D-ribofuranosyl)uracil (VI). **Alcoholysis** of 17.5 mg. VI 3 hrs. in 1.5 ml. 0.02M MeONa-MeOH gave 10 mg. 6-aza-5-methyluridine 5'-(diphenyl phosphate). Hydrogenolysis of 70 mg. VI over 420 mg. PtO₂ in EtOH 20 hrs. gave 6-aza-2',3'-di-O-hexabydro-benzoyl-5-methyluridine 5'-phosphate, yielding, on **methanolysis** as above, IV, isolated as the Ba and dicyclohexylammonium salts. IV was also obtained in 40-mg. yield by total hydrogenolysis of 87 mg. V. The structure and β-D-configuration on

the C-1 atom of the sugar moiety of IV was proved by enzymic dephosphorylation by calf intestine alkaline phosphatase in Tris buffer and 0.005M MgSO₄ solution, yielding 6-aza-5-methyluridine. The described procedures suggest general applicability for the synthesis of 6-aza-1-glycosyluracils, especially of nucleotides derived from 5-substituted 6-azauracils, since no hydrogenation of the 6-azauracil ring occurs on hydrogenolysis.

AB Alkoxysilanes (R1O)R2R3Si(CH2)3X [3, R1 = C1-15 (un)branched alkyl or C2-8 alkoxyalkyl; R2, R3 = C1-6 (un)branched alkyl, Ph; X = Cl, Br, I, substituted benzenesulfonate, alkanesulfonate, carboxylate; most preferred, X = Cl], useful as intermediates in production of polysulfides (R1O)R2R3Si(CH2)3Sn(CH2)3SiR2R3(OR1) (4, n = 1.5-5, same R1-R3) (no data), were prepared by controlled (dis)continuous alcoholysis of chlorosilanes ClR2R3Si(CH2)3X with alcs. R1OH in inert (cyclo)alkane solvents, chosen from hexane, heptane, cyclohexane and their mixts. with pentane, having b.p. close to that of the alc. and applied in amts. to provide 5-30 wt% of the alc. concentration in the solution The forming hydrochloric acid, which causes

undesired side-reactions of the chlorosilane condensation, is removed from reaction by degassing during reflux of the volatile reaction components.

The polysulfides 4 may be then obtained by reaction of the haloalkylsilanes 3 with alkali metal polysulfides. In an example, ethanolysis of ClMe₂Si(CH₂)₃Cl (1.75 mol) was performed at 94° in a stirred reactor equipped with reflux column by dissoln. of the silane in 300 g of cyclohexane and addition of ethanol in a discontinuous manner in two portions (73.4 and 26.6% of the total amount of 2.63 mol; during 40 and 30 min, resp.), each followed by a reflux periods of 1 and 1.5 h, resp.; the basic work-up included addition of 0.5 g of gaseous NH₃ and distillation, affording

(EtO)Me₂Si(CH₂)₃Cl in 97% yield with 100% conversion of the chlorosilane.

AB A review. Unlike metal-ion-catalyzed hydrolysis processes, metal-ion-catalyzed **methanolysis** processes have received scant attention in the literature particularly from the standpoint of mechanistic studies. **La3+**, introduced into methanol solution as its triflate or perchlorate salt, is particularly effective in promoting **methanolysis** reactions of unactivated and activated esters, phosphate triesters, and activated amides such as acetyl imidazoles and lactams. Studies of the kinetics of **methanolysis** of these substrates as a function of solution pH and [La3+] indicate that the solution comprises **lanthanum** dimers with one to five associated methoxides (La23+(-OCH3)1-5), the most catalytically active form being La23+(-OCH3)2, which is produced at near neutral pH in methanol (8.4). Mechanisms for all the acyl and phosphoryl transfer reactions are proposed where the metal ion serves a dual role of acting as a Lewis acid to activate the C=O or P=O system to nucleophilic attack by a metal-coordinated methoxide nucleophile. In cases where direct comparisons can be made, the La23+ catalyst system is more active for the **methanolysis** of nonactivated substrates than for activated substrates. Another general characteristic of this system is that the catalytic rate constant for the metal complex exceeds the second-order rate constant for free methoxide, in some cases by as much as 4600-fold. Overall the catalytic effects exhibited by the La23+ system is spectacular for such substrates as **paraoxon**, where as little as 2 mmol L⁻¹ La(OTf)3 in the presence of equimolar NaOCH3 accelerates the **methanolysis** by 109-fold relative to the background reaction at neutral pH and ambient temperature

AB The methanolyses of a series of O,O-di-Et O-aryl phosphates (2,5) and O,O-di-Et S-aryl phosphorothioates (6) promoted by methoxide and two metal ion systems, $(\text{La}^{3+})_2(-\text{OCH}_3)_2$ and $4:\text{Zn}^{2+}:-\text{OCH}_3$ (4 = 1,5,9-triazacyclododecane) has been studied in methanol at 25 °C. Bronsted plots of the log k_2 values vs. sspK_a for the phenol leaving groups give β_{lg} values of -0.70, -1.43 and -1.12 for the methanolysis of the phosphates and -0.63, -0.87 and -0.74 for the methanolysis of the phosphorothioates promoted by the methoxide, La^{3+} and Zn^{2+} systems resp. The kinetic data for the metal-catalyzed reactions are analyzed in terms of a common mechanism where there is extensive cleavage of the P-XAr bond in the rate-limiting transition state. The relevance of these findings to the mechanism of action of the phosphotriesterase enzyme is discussed.

AB The **La3+-catalyzed methanolysis** of two phosphorothioate derivs., O,O-di-Et S-(p-nitrophenyl) phosphorothioate (4a) and O,O-di-Et S-Ph phosphorothioate (4b) was studied as a function of [La3+] and sspH in methanol solvent. In both cases the kinetics of catalyzed **methanolysis** maximize at sspH 9.1 and a detailed anal. indicates that the dominant species responsible for catalysis are dimers formulated as **La3+2(-OCH3)2** and **La3+2(-OCH3)4**. The catalysis is compared with that seen for the corresponding phosphate esters, namely **paraoxon** (3a) and O,O-di-Et Ph phosphate (3b) for which **La3+** catalysis is slightly better and markedly worse than for 4a and 4b, resp. Overall, at sspH 9.1, a 2 mmol dm-3 solution of La(OTf)3 with equimolar NaOCH3 provides accelerations of 2.2 + 108-fold, 9.7 + 106-fold, and 9.3 + 106-fold for **methanolysis** of 3a, 4a, and 4b, relative to the background reaction of methoxide reacting with the three substrates. In each case, the P-containing product of the reactions is exclusively di-Et Me phosphate. Turnover expts. with 6-fold and 100-fold excesses of 4a and 4b, resp., **methanolized** in the presence of .apprx.10 mmol dm-3 **La3+** and equimolar NaOCH3, indicate that the reactions are essentially complete within 103 s and 70 min, resp. The latter turnover experiment with 4b corresponded to 100 turnovers in 70 min and an overall reaction t1/2 of 8 min. A common mechanism of reaction is postulated for each of the substrates which involves Lewis acid coordination of one of the **La3+** to the P=O unit, followed by nucleophilic attack by the second **La3+--OCH3**.

DOCUMENT TYPE: Journal

LANGUAGE: English

AB The methanolyses of two neutral phosphorus triesters, **paraoxon** (1) and fenitrothion (3), were investigated as a function of added Zn(OTf)₂ or Zn(ClO₄)₂ in methanol at 25 °C either alone or in the presence of equimolar concns. of the ligands phenanthroline (4), 2,9-dimethylphenanthroline (5), and 1,5,9-triazacyclododecane (6). The catalysis requires the presence of methoxide, and when studied as a function of added NaOCH₃, the rate consts. (k_{obs}) for **methanolysis** of Zn²⁺ alone or in the presence of equimolar 4 or 5 maximize at

different $[-\text{OCH}_3]/[\text{Zn}^{2+}]_{\text{total}}$ ratios of 0.3, 0.5, and 1.0, resp. Plots of k_{obs} vs $[\text{Zn}^{2+}]_{\text{total}}$ either alone or in the presence of equimolar ligands 4 and 5 at the $[-\text{OCH}_3]/[\text{Zn}^{2+}]_{\text{total}}$ ratios corresponding to the rate maxima are curved and show a nonlinear dependence on $[\text{Zn}^{2+}]_{\text{total}}$. In the cases of 4 and 5, this is explained as resulting from formation of a nonactive dimer, formulated as a bis- μ -methoxide-bridged form ($\text{L}:\text{Zn}^{2+}(-\text{OCH}_3)_2\text{Zn}^{2+}:\text{L}$) in equilibrium with an active monomeric form ($\text{L}:\text{Zn}^{2+}(-\text{OCH}_3)$). In the case of the $\text{Zn}^{2+}:\text{6}$ system, no dimeric forms are present as can be judged by the strict linearity of the plots of k_{obs} vs $[\text{Zn}^{2+}]_{\text{total}}$ in the presence of equimolar 6 and $-\text{OCH}_3$. Anal. of the potentiometric titration curves for Zn^{2+} alone and in the presence of the ligands allows calcn. of the speciation of the various Zn^{2+} forms and shows that the binding to ligands 4 and 6 is very strong, while the binding to ligand 5 is weaker. Overall the best catalytic system is provided by equimolar Zn^{2+} , 5, and $-\text{OCH}_3$, which exhibits excellent turnover of the **methanolysis** of **paraoxon** when the substrate is in excess. At a concentration of 2 mM in each of these components, which sets the pH of the solution at 9.5, the acceleration of the **methanolysis** of **paraoxon** and **fenitrothion** relative to the methoxide reaction is 1.8×10^6 -fold and 13×10^6 -fold, resp. A mechanism for the catalyzed reactions is proposed which involves a dual role for the metal ion as a Lewis acid and source of nucleophilic Zn^{2+} -bound $-\text{OCH}_3$.

LANGUAGE: English

AB The kinetics of methanolysis of the title compound fenitrothion (3) were
 studied in the presence of Cu²⁺, introduced as Cu(OTf)₂, in the
 presence of 0.5-1.0 equivalent of methoxide and in the presence of 1.0
 equivalent

of a ligand such as bipyridyl (5), phenanthroline (6) or
 1,5,9-triazacyclododecane (4). In all cases the active species involve
 Cu²⁺(-OCH₃). In the case of added strong-binding ligands 5 or 6,
 a plot of the observed rate constant for methanolysis of 3 vs. [Cu²⁺

+] $[\text{Cu}^{2+}]_{\text{total}}$ gives a curved line modeled by a process having a $[\text{Cu}^{2+}]^{1/2}$ dependence consistent with an active monomeric species in equilibrium with an inactive dimer i.e. $\{[\text{LCu}^{2+}(-\text{OCH}_3)]_2\}$. In the case of the added strong binding ligand 4, the plot of the observed rate constant for methanolysis of 3 vs. $[\text{Cu}^{2+}]_{\text{total}}$ gives a straight line consistent with the catalytically active species being $4\text{Cu}^{2+}(\text{OCH}_3)$ which shows no propensity to form inactive dimers. Turnover expts. where the $[3] > [\text{Cu}^{2+}]_{\text{total}}$ indicate that the systems are truly catalytic. In the optimum case a catalytic system comprising 1 mM of the complex $4\text{Cu}^{2+}(-\text{OCH}_3)$ catalyzes the methanolysis of 3 with a $t_{1/2}$ of .apprx.58 s accounting for a 1.7×10^9 -fold acceleration relative to the background reaction at near neutral sspH (8.75).

AB A process for the preparation of a glossy slow release insecticidal paint
(SRIP) for insect control comprises subjecting a long chain oil to the
step of alcoholysis with a perhydroxy compound in the presence of

a catalyst, for example, lithium hydroxide, at the temperature of 150 to 300 °C, subjecting the resulting product to the step of polycondensation/esterification with an aromatic or aliphatic anhydride, adding to the reaction product so obtained of conventional insecticides in the amount of 0.5 to 1.5 parts, along with a mixture of a pigment and a curing agent.

LANGUAGE: English

AB The **methanolysis** of the insecticide **paraoxon**

(2) was investigated in methanol solution containing varying [La(OTf)₃] (OTf = -OS(O)CF₃) as a function of sspH at 25°. Plots of the pseudo-first-order rate consts. (k_{obs}) for **methanolysis** as a function of [La(OTf)₃]_{total} were obtained under buffered conditions from sspH 5.15 to 10.97, and the slopes of the linear parts of these were used to determine the second-order rate consts. (k_{2obs}) for the La₃ +-catalyzed **methanolysis** of 2. Detailed anal. of the potentiometric titration data of La(OTf)₃ in methanol through fits to a multicomponent equilibrium mixture of dimers of general stoichiometry La₃ +2(-OCH₃)_n, where n assumes values of 1-5, gives the equilibrium distribution

of each as a function of sspH. These data, when fit to a second expression describing k_{2obs} in terms of a linear combination of individual rate consts. $k_{22:1}$, $k_{22:2}$ $k_{22:n}$ for the dimers, allow one to describe the overall catalytic profile in terms of the individual contributions.

The most catalytically important species are the three dimers La_3

$+2(-OCH_3)_1$, $La_3+2(-OCH_3)_2$, and $La_3+2(-OCH_3)_3$. The

catalysis of the **methanolysis** of 2 is spectacular: a 2 +

10^{-3} M solution of $[La_3+]_{total}$, at neutral sspH, affords a 109-fold

acceleration relative to the base reaction ($t_{1/2} \approx 20$ s at sspH

8.2) with excellent turnover. A mechanism of the catalyzed reaction

involving the $La_3+2(-OCH_3)_2$ species is proposed.

DOCUMENT TYPE: Journal

LANGUAGE: English

AB The interaction of **La³⁺** with di-Ph phosphate, Me p-nitrophenyl phosphate, and bis(p-nitrophenyl) phosphate (4, 5, and 3) and the ensuing catalysis of methanolysis was studied in methanol under completely homogeneous conditions of known sspH. ³¹P NMR shows that phosphates 3 and 4 are each associated with **La³⁺** as a rapidly interconverting mixture of complexes having 2:1, 1:1 (or 2:2), and 1:2 stoichiometry. At [**La³⁺**] > 2 + 10⁻⁴ M, the kinetically dominant species in the sspH regions of interest are phosphate-bound **La³⁺** dimers having

2-5 associated methoxides. Potentiometric titration reveals that 4 mM La^{3+} alone in MeOH exhibits two apparent sspKas at 7.86 and 10.44 consuming 1 and 1.5 CH_3O^- per metal, the suggested structures being La^{3+} dimers with first two and then five associated methoxides. In the presence of 0.5 equiv of 4 the potentiometric titration reveals strong complexation of 4 to La^{3+} and a profile with apparent sspKas at 7.8 and 11.1 consuming 1 and 1.5 CH_3O^- per metal corresponding to phosphate-bridged La^{3+} dimers with first two and then five associated methoxides. Methanolysis of 3-5 is strongly accelerated by La^{3+} . At sspH 8.9 or 11.1, resp., as little as 5×10^{-4} M $\text{La}(\text{OTf})_3$ accelerates the methanolysis of 3 or 4 by 1010-fold relative to the background reaction. Detailed kinetic studies of the methanolysis of 5 at varying $[\text{La}^{3+}]$ and sspH indicate that both La^{3+} monomers and dimers with associated methoxides are reactive species. The rate consts. for La^{3+} monomer and dimer catalysis of the methanolysis of 5 are dependent on sspH, the slopes of the log plots being 0.35 and 0.5, resp. A scheme is proposed to account for the non-first-order dependence on $[\text{CH}_3\text{O}^-]$ wherein the $\text{La}^{3+}(\text{CH}_3\text{O})_x + 5 \xrightarrow{\text{dimer}} \text{La}^{3+}(\text{CH}_3\text{O})_x:5$ and $(\text{La}^{3+})_2(\text{CH}_3\text{O})_y + 5 \xrightarrow{\text{dimer}} 5:(\text{La}^{3+})_2(\text{CH}_3\text{O})_y$ equilibrium are driven to the left with increasing nos. of associated methoxides and that attack on these complexes, whether by external or metal-associated methoxide, is slower due to the reduced net pos. charge on the complex.

AB The title polymers are prepared by alcoholysis of ester-terminated polyoxyalkylenes and alcs. in the presence of composite metal oxide catalysts (consisting of alkaline earth metal oxides and alumina, silica, zinc oxide and mixts.), and separating the produced OH-terminated polyoxyalkylene from the catalysts. A catalyst was prepared by calcination of a dried mixture of alumina and $\text{Ca}(\text{NO}_3) \cdot 4\text{H}_2\text{O}$ to give CaO and Al_2O_3 . Polytetramethylene glycol acetate was reacted with MeOH using the above catalyst to give polytetramethylene glycol.

AB Hydroxy group end-capped polyether glycols for manufacture of thermoplastic
 urethanes and copolyester ethers, are prepared by alcoholysis of ester
 end-capped polyalkylene ether in the presence of a highly active, mixed
 metal oxide catalyst, containing an alkaline earth metal oxide and oxide of

Al, Si

or/and Zn, which can be fabricated into shaped articles for a slurry or a
 fixed bed reactor and is easily separated from product. Thus,
 polytetramethylene ether acetate (I) 40, methanol 45.4 and a catalyst
 prepared by drying and calcining Ca(NO₃)₂·4H₂O and γ-Al₂O₃ (CaO 20 and
 Al₂O₃ 80%) 1 g were reacted at 55° for 150 min in a slurry reactor
 to give a product with I conversion 84.6%.

AB The title compound is prepared by catalytic addition reaction of trichlorosilane

to allyl chloride, alcoholysis of the (3-chloropropyl)trichlorosilane thus

formed to give (3-chloropropyl)trimethoxysilane, followed by condensation reaction with ethylenediamine such that the addition reaction of trichlorosilane with allyl chloride occurs in presence of a catalyst consisting of a **platinum** complex $\text{Pt}(\text{PPh}_3)_2\text{X}$ (X = ethylene, $\text{CH}_2:\text{CHSiY}_3$, Y = Me, EtO). Thus, in an example, the title compound is obtained in 85% yield when $\text{Pt}(\text{PPh}_3)_2[\text{CH}_2:\text{CHSi}(\text{OEt})_3]$ was used as the catalyst in silylation of 0.4 mol allyl chloride with 0.4 mol trichlorosilane.

ACCESSION NUMBER: 1993:439636 HCAPLUS

DOCUMENT NUMBER: 119:39636

TITLE: Reactions of **lanthanide** nitrates with
dimethylbenzoylphosphonate

AUTHOR(S): Platt, Andrew W. G.

CORPORATE SOURCE: Chem. Div., Staffordshire Univ., Stoke-on-Trent, ST4
2DE, UK

SOURCE: Polyhedron (1993), 12(5), 467-72

CODEN: PLYHDE; ISSN: 0277-5387

DOCUMENT TYPE: Journal

LANGUAGE: English

AB The reactions between $\text{Ln}(\text{NO}_3)_3$ ($\text{Ln} = \text{La}, \text{Ce}, \text{Yb}$) and $(\text{MeO})_2\text{P}(\text{:O})\text{Bz}$ in MeOH
 were studied. The products of the reaction are $(\text{MeO})_2\text{P}(\text{:O})\text{H}$,
 $[(\text{MeO})_2\text{P}(\text{:O})]_2\text{C}(\text{OH})\text{Ph}$ and BzOMe . At high concns. of reactants
 $\text{Ln}(\text{NO}_3)_3\{[(\text{MeO})_2\text{P}(\text{:O})_2\text{P}(\text{:O})]_2\text{C}(\text{OH})\text{Ph}\}_2$ are formed ($\text{Ln} = \text{La}, \text{Ce}$) while loss
 of NO_3^- occurs for the heavier metals giving $\text{Ln}(\text{PO}_4)\{\text{MeO})_2\text{P}(\text{:O})\text{H}\}_2 \cdot \text{H}_2\text{O}$ (Ln
 $= \text{Yb}$). The kinetics of the reaction in dilute solution were studied and a
 mechanism proposed. Derivation of a rate equation from the full mechanism
 is not possible but the kinetics data were fitted to an approx. expression
 and the results compared with 1st order anal. Supporting evidence for the
 proposed mechanism (mainly ^{31}P NMR spectroscopy) is presented.

AB The influence of chemical structure of ester alkyl groups of monoalkyl
isopropylphosphonates on extraction behavior of rare earths was studied. The
monoalkyl isopropylphosphonate bearing a β -substituted ester alkyl

group shows a high Kex value, which is evidently depressed, usually by 2 orders of magnitude, by introducing a branch chain on the α -position of the ester alkyl group. The steric effect of the ligand is usually enhanced due to the characteristic lanthanide contraction. The extraction chemical of rare earths by monoamylnonyl isopropylphosphonates

(MANPP)

was studied in detail. The thermodyn. function was estimated and the "tetrad effect" between Kex value or ΔG value and atomic number was observed. In addition, the composition and structure of the coordinated compound was

studied. As

demonstrated by the exptl. data, the extractive separation of Sm and Nd by MANPP in chloride solution was better than that in the nitrate system.

 AB The bis(2,4,4-trimethylpentyl)phosphinic acid (Cyanex-272) and sodium
 diethyl- dithiocarbamate (NaDDC) ligands were used to extract of metal ions
 (Cd2+, Co2+, Cu2+, Pb2+, Zn2+) in supercrit. CO2.
 Expts. showed a strong synergistic effect and better extraction efficiency if
 the two ligands were used together. In-situ UV-visible observation
 indicates that NaDDC in the water/supercrit. CO2 started to **decomp**
 . slowly. The synergistic effect seems to come from the deprotonation of
 the **organophosphorus** ligand by amines from the **decompd**
 . NaDDC. The enhancing role of amines was confirmed using the mixture of
 Cyanex-272 and diethylamine(DEA) in the metal extraction

AB Methods and kits for **decomposing organophosphorus** compds. in nonaq. media at ambient conditions are described. Insecticides, pesticides, and chemical warfare agents can be quickly **decomposed** to nontoxic products. The method comprises combining the **organophosphorus** compound with a nonaq. solution, preferably an alc., comprising metal ions and at least a trace amount of alkoxide ions. In a 1st preferred embodiment, the metal ion is a La ion. In a 2nd preferred embodiment, the metal ion is a transition metal.

AB **Organophosphites** are a versatile component of liquid PVC heat stabilizers and stabilize PVC through a variety of mechanisms.

Organophosphites can **decompose** peroxides, replace labile chlorines on the PVC backbone, scavenge HCl (via the Arbuzov rearrangement), complex Lewis acids, and add to double bonds. This paper attempts to identify the relative contributions of these mechanisms in both model systems and flexible PVC formulations.

AB Novel Zn(II) **organophosphonates** with coordinated 2,2'-bipyridyl (2,2'-bipy, C10H8N2) and 1,10-phenanthroline (phen, C12H8N2) ligands (with the proposed formulations: Zn(O3PPh)(C12H8N2), **Zn2**(O3PR)2(C12H8N2) (R = C6H5CH2, C2H5, CH3), and **Zn2**(O3PR)2(C10H8N2)(H2O) (R = C6H5, C6H5CH2)) was prepared and characterized. The amine derivs. have the same 1:1 metal/P ligand ratio as the parent Zn(II) **organophosphonates**, and, with the exception of the phen derivative of Zn(II) phenylphosphonate, Zn(O3PPh)(C12H8N2), all of the amine derivs. possess a metal/P/amine ratio of 2p2:1 where one amine ligand is coordinated to every two Zn atoms. Elemental analyses, FTIR, TGA, XPS, and solid-state 31P/13C MAS NMR data are consistent with the proposed formulations. Powder XRD measurements show Zn(O3PPh)(C12H8N2) and **Zn2**(O3PCH2C6H5)2(C12H8N2) to be layered, whereas the other complexes are nonlamellar materials. XPS data suggests that the N atoms of the amine ligands are coordinated to the Zn center in an unsym. manner.

PUBLISHER: Research Journal of Chemistry and Environment

DOCUMENT TYPE: Journal

LANGUAGE: English

AB This work characterized an isolate of *Proteus vulgaris* from Ganges River water of the Sreerampore region near Kolkata, India. The isolate exhibited resistance to ampicillin, chloramphenicol, tetracycline, nalidixic acid, and streptomycin (AR, CR, TR, NxR, SR) but sensitivity to ciprofloxacin, gentamycin, and norfloxacin (CiR, GR, NR). The bacteria tolerated heavy metals: Hg2+, Cd2+, and Cu2+ up to concns. of 0.25, 3, and 10 mM resp. A **pesticide** resistance study demonstrated min. inhibitory concns. (µg/mL) for 4 **pesticides**: dimethoate, 30% EC [D(10)]; methyl parathion, 50% EC [M (50)]; endosulfan, 35% EC [E(100)]; and carbaryl, 50% EC [Cb(50)]. This strain, when used as donor in a conjugation experiment with a plasmid-less *Escherichia coli* C 600 (NxR F-) recipient, showed the resistance to antibiotics, heavy metals, and **pesticides** was not transferred. Resistance to C, T, Cd2+, Hg2+, and D was altered following plasmid curing with 0.1 mg/mL

ethidium bromide (EB). The *P. vulgaris* strain rendered resistivity toward D to the otherwise sensitive *E. coli* C600 strain in a deoxycholate agar (DCA) plate containing D (5 µg/mL). The cured strain of *P. vulgaris* did not exhibit such characteristics. Following the alkaline lysis method, the wild type of *P. vulgaris* harbored a single plasmid, but the cured mutant strain failed to exhibit any plasmid. Results suggested the *P. vulgaris* plasmid encoded the resistance pattern of "C T C2+ Hg2+ D" and was associated with the degradation of D.

AB The stability of commonly used pesticides in plant sample exts. was
evaluated. Matrixes differing in the character of coexts. were
represented by wheat, oranges and white cabbage. After homogenization
with Et acetate and anhydrous sodium sulfate, spiked filtrates were stored
for 60 days at 20°C or 40°C. The decrease of concns. was
observed at 20°C after 40 days for chlorothalonil and iprodione in
cabbage exts. and some degradation was observed for most **organophosphates**
, iprodione and pirimicarb in orange exts. At increased temperature
(40°C), degradation of most pesticides in the orange and cabbage exts.
was observed. No **decomposition** was noticed for synthetic pyrethroids in
all tested exts. The stability of pesticides in wheat exts. was
distinctly higher than that in other exts. Most pesticides are stable
enough to store plant sample exts. several weeks prior to further
handling, or to use them as calibrants to avoid matrix-induced enhanced GC
response. Some degradation of pesticides, in "pure" Et acetate solns. was
noticed only for some **organophosphates** (mevinphos,
methamidophos, dichlorvos, heptenophos, pirimiphos-methyl) after 60 days
at 40°C.

AB The stability of 89 pesticides (17 organochlorine, 33 **organophosphorus**, 8 pyrethroid, 12 carbamate, and 19 other pesticides) in 6 kinds of organic solvents (methanol, ethanol, 2-propanol, Et acetate, n-hexane, and acetone) was investigated using gas chromatog./mass spectrometry(GC/MS). All of the investigated pesticides were stable in all of the tested organic solvents during storage for 6 h at room temperature in

the dark except captafol, captan, phosmet, chinomethionat, and dicofol. However, the losses of captafol, captan, phosmet, and chinomethionat were observed in methanol. The losses of captafol, captan, and phosmet were also observed in ethanol. Moreover, the loss of dicofol was observed in acetone. The loss of captafol dissolved in methanol at a concentration of 2 µg/mL was faster than those of captan, phosmet, and chinomethionat; the residual captafol was 75% after 30 min of storage. Dicofol dissolved in acetone also decreased during storage in a refrigerator. 4,4'-Dichlorobenzophenone (DCBP) and chlorobutanol were detected in the acetone solution of dicofol after storage. Furthermore, it was found that dicofol was **decomposed** by acetone at an injection port, and DCBP and chlorobutanol were formed when it was injected into GC with acetone.

AB This report is part of a study to immobilize actinide ions in the near-surface environment of a radioactive waste disposal site by reacting actinides with **organophosphorus** complexants that **decomp** to inert, stable phosphates. In the initial phase of the study, Gd³⁺ and Nd³⁺ were used as models for Pu³⁺, Am³⁺, and Cm³⁺; phytic acid was chosen as the **organophosphorus** complexant. The goal of this part of the project was to determine the bonding in the precipitated **lanthanide** phytates.

AB A new approach to the remediation of actinide contamination is described. A hydrolytically unstable **organophosphorus** compound, phytic acid, is introduced into the contaminated environment. In the short term (up to several hundred years), phytate acts as a cation exchanger to absorb mobile actinide ions from ground waters. Ultimately, phytate

decomps. to release phosphate and promote the formation of insol. phosphate mineral phases, considered an ideal medium to immobilize actinides, as it forms compds. with the lowest solubility of any candidate mineral species. This overview will discuss the rate of hydrolysis of phytic acid, the formation of **lanthanide/actinide** phosphate mineral forms, the cation exchange behavior of insol. phytate, and results from laboratory demonstration of the application to soils from the Fernald site.

AB The reaction of ZnEt_2 with $\text{HO}(\text{O})\text{P}(\text{OtBu})_2$ gives the insol. polymer $\{\text{Zn}[\text{O}_2\text{P}(\text{OtBu})_2]_2\}_n$ (1). In the presence of slight amts. of H_2O , this reaction produces good yields of the oxo-centered tetranuclear cluster $\text{Zn}_4(\mu_4\text{-O})[\text{O}_2\text{P}(\text{OtBu})_2]_6$ (2), which was characterized by x-ray crystallog. 2 is thermally labile and eliminates isobutene and H_2O over the temperature range 130-220°. The ceramic yield at 900° corresponds to the theor. yield for a $\text{Zn}_4\text{P}_6\text{O}_{19}$ material, and the observed products at this temperature are $\alpha\text{-Zn}_2\text{P}_2\text{O}_7$ and $\beta\text{-Zn}(\text{PO}_3)_2$ (by XRD). When heated in EtOH at 85° for 30 h, 2 converts to polymer 1 and ZnO . This transformation is facilitated by acids, which allow the conversion to occur at room temperature. Polymer 1, characterized by x-ray crystallog., adopts a zigzag structure with Zn atoms linked alternately by one and then three bridging phosphate groups. This structure is therefore different from that adopted by the other two organozincophosphate $\{\text{Zn}[\text{O}_2\text{P}(\text{OR})_2]_2\}_n$ polymers that are known, which exist as linear chains with the Zn atoms bridged by two phosphate groups. Polymer 1 undergoes a quant. pyrolytic conversion to $\beta\text{-Zn}(\text{PO}_3)_2$. Diffusion of a toluene solution of 2 into a CH_2Cl_2 solution of 1,6-hexanediamine produces a coordination network $\{\text{Zn}[\text{O}_2\text{P}(\text{OtBu})_2]_2[\text{H}_2\text{N}(\text{CH}_2)_6\text{NH}_2]\}_n$ (3), with elimination of ZnO . The network structure of 3 consists of $\{\text{Zn}[\text{O}_2\text{P}(\text{OtBu})_2]_2[\text{H}_2\text{N}(\text{CH}_2)_6\text{NH}_2]\}_n$ polymer strands interconnected via H bonds between the N-H and P=O groups to form layers stacked along the crystallog. b axis. Each polymer chain contains four-coordinate Zn atoms bonded to two monodentate di-tert-butylphosphate ligands and linked by 1,6-hexanediamine groups. Slabs of the layered structure are held together by a dense array of H bonds involving the N-H and P=O functionalities. These layers possess Zn phosphate/1,6-hexanediamine cores and are coated with tert-Bu groups such that there are only van der Waals interactions between layers. TGA and XRD studies show that 3 undergoes thermolysis to a mixture of crystalline $\alpha\text{-Zn}_2\text{P}_2\text{O}_7$ and $\beta\text{-Zn}(\text{PO}_3)_2$.

AB A method is being developed to transform actinide ions in the near surface environment to less soluble, less reactive, thermodynamically stable phosphate minerals phases through application of **organophosphorus** complexants. These complexants **decompose** slowly, releasing phosphate to promote the formation of stable phosphate mineral phases, particularly with the more soluble trivalent, pentavalent, and hexavalent actinide ions. The complexant of choice, myo-inositol(hexakisphosphoric acid) or phytic acid, is a natural product widely used as a nutritional supplement. Phytic acid **decomps.** slowly in the absence of microbiol. effects, crystalline phosphate minerals are formed as a consequence of its **decomposition**, and the formation of actinide (**lanthanide**) phosphates reduces the solubility of trivalent and hexavalent metal ions under environmental conditions.

 AB A new method to reduce the potential environmental mobility of actinides by conversion to insol. mineral forms is under development. The method is comprised of the addition of a water-soluble, hydrolytically unstable **organophosphorus** complexant into the groundwater. The complexant functions initially as a cation exchanger but ultimately **decomps** . to release phosphate and promote the formation of insol. actinide phosphates. In this report, we discuss the effect of phosphate, calcium ion, pH, and selected chelating agents on the concentration of **lanthanide** and actinide cations in actual and simulated geomedia as monitored using radiotracer techniques. In addition, the cation exchange behavior of the preferred complexant (phytic acid) in simulated soil columns is examined. Work performed under the auspices of the U.S. Department of Energy, Office of Environmental Waste management, Efficient Sepns. and Processes Program under contract number W-31-109-ENG-38.

AB A method is being developed to transform actinide ions in the near surface environment to less-soluble, less-reactive, thermodynamically stable phosphate mineral phases through the application of surface active **organophosphorus** complexants. These **organophosphorus** species are designed to **decompose** slowly in the environment to release phosphate. The slow-release of phosphate promotes the formation of stable mineral phases. In particular, the more soluble actinide species, the trivalent, pentavalent and hexavalent oxidation states, are targeted. The complexant of choice is myoinositol(hexakisphosphoric acid) or phytic acid. Phytic acid is a natural product widely used as a nutritional supplement. We have determined that phytic acid **decomps.** at a convenient rate, that crystalline phosphate minerals are formed as a consequence of the **decomposition**, and that the **lanthanide** /actinide phosphates reduce radionuclide solubility under environmental conditions. This technique also may have important applications in the stabilization of the tailings piles produced as a result of mining operations for uranium/thorium or strategic metals. Work Performed under the auspices of the Efficient Sepns. Program of the U.S. Department of Energy under contract W-31-109-ENG-38.

AB Dimethyl-2,2-dichlorovinyl phosphate (DDVP) and dimethyl-2,2,2-trichlor-1-hydroxyethyl phosphonate (DEP) were degraded in the presence of suspended TiO₂ by illumination with a super-high pressure Hg lamp or by exposure to sunlight. Pt-loading to TiO₂ enhanced the degradation rates 4.5- and 6-fold for DDVP and DEP, resp. The addition of H₂O₂ to the suspension also enhanced the rates 10- and 2-fold for the former and latter, resp. The final degradation products were Cl⁻, PO₄³⁻, H⁺, and CO₂, and one of the intermediates was HCHO.

AB The **decomposition** of a model **organophosphonate** compound, di-Me methylphosphonate (DMMP), by Pd(111) and Ni(111) surfaces has been studied by using Auger spectroscopy and temperature-programmed reaction

spectroscopy. In both cases, in the absence of O₂, thermal **decomposition** of DMMP occurs [Pd, below 300 K; Ni, below 340 K] based on the observation of desorption-limited H₂ and CO evolution. Phosphorus is deposited on both Pd(111) and Ni(111) surfaces following the DMMP **decomposition**. Oxidation at 1075 K removes the surface phosphorus on Pd(111). On Ni(111), however, surface phosphorus cannot be removed by oxidation at 1075 K, nor is preoxidized Ni(111) active for phosphorus removal at 1075 K. By comparison with similar expts. on Mo(110), it appears that the early transition metals may be more suitable for the catalytic oxidation of **organophosphonate** compds., on the basis of the lower temperature for sustained removal of surface phosphorus by oxygen on Mo(110) [900 K] compared to Pd(111) [1075 K].

AB Inelastic electron tunneling spectroscopy has been used to characterize the adsorption and **decomposition** of a number of organo-phosphonate esters on aluminum oxide surfaces as a function of surface coverage and surface temperature. Technol. advances have been made in the measurement of inelastic electron tunneling spectra including a rapid spectral measurement technique and a simple technique for background removal. A microreactor which allows rates of heterogeneously catalyzed surface reactions to be measured at pressures from below .0000001 Torr to one atmospheric

has been constructed. This microreactor has been used to measure the rate of **decomposition** of ammonia, the inhibition by hydrogen in the rate of ammonia **decomposition**, and the rate of exchange of deuterium into NH₃ on a platinum surface. A microscopic model has been developed that describes these reactions for pressures between .0000001 and 1 Torr and temps. between 450 and 1250 K.

AB At pH 7 and 50°, the half life of volaton (I) [14816-18-3], Gardona (II) [22248-79-9], and Basudin (III) [333-41-5] was 21 h, 12 and 9 days, resp. At pH 3 and 5° or 60°, the half life of II was 90 and 45 days, resp., whereas that of III was 51 days at 35°. At pH 10, 50% of II and III **decomposed** within 24 h at 60 and 35°, resp. CuCl₂ hastened the hydrolysis of III more than did ZnSO₄. Cu oxychloride at 0.6% inhibited, whereas 0.1% CuSO₄ hastened, the **decomposition** of I, III, and Dursban [2921-88-2]. Acid and neutral hydrolysis dealkylates the **organophosphorus** insecticides, whereas alkaline hydrolysis breaks the P-O bond. Thus, at pH >8 Sumithion [122-14-5] was degraded to 3-methyl-4-nitrophenol [2581-34-2] and III to 2-isopropyl-4-methyl-6-oxopyrimidine [2814-20-2], whereas at pH <7 Sumithion was converted to demethylsumithion [4321-64-6] and I, II, III, carbophos [121-75-5], Actellic [29232-93-7], and Dursban lost their corresponding alkyls. Foliar sprays with microfertilizers containing Cu, Zn, and Mn hastened detoxication of I, III, and carbophos on the foliar surface and in whole cabbage plants, whereas B and Mo retarded the **decomposition**. Com. application with Vuxal (a B-Mn fertilizer) retarded the I degradation in sugar beet leaves by 8-12 days. Fungicidal sprays with CuSO₄ hastened, whereas Cu oxychloride delayed, I degradation in potato leaves. The microfertilizers altered the rate of insecticide degradation on the surface of foliar cuticles more than inside the plant cells.
